

Epigenetic genome control by RNAi and transposon-derived proteins

Shiv Grewal, Ph.D.

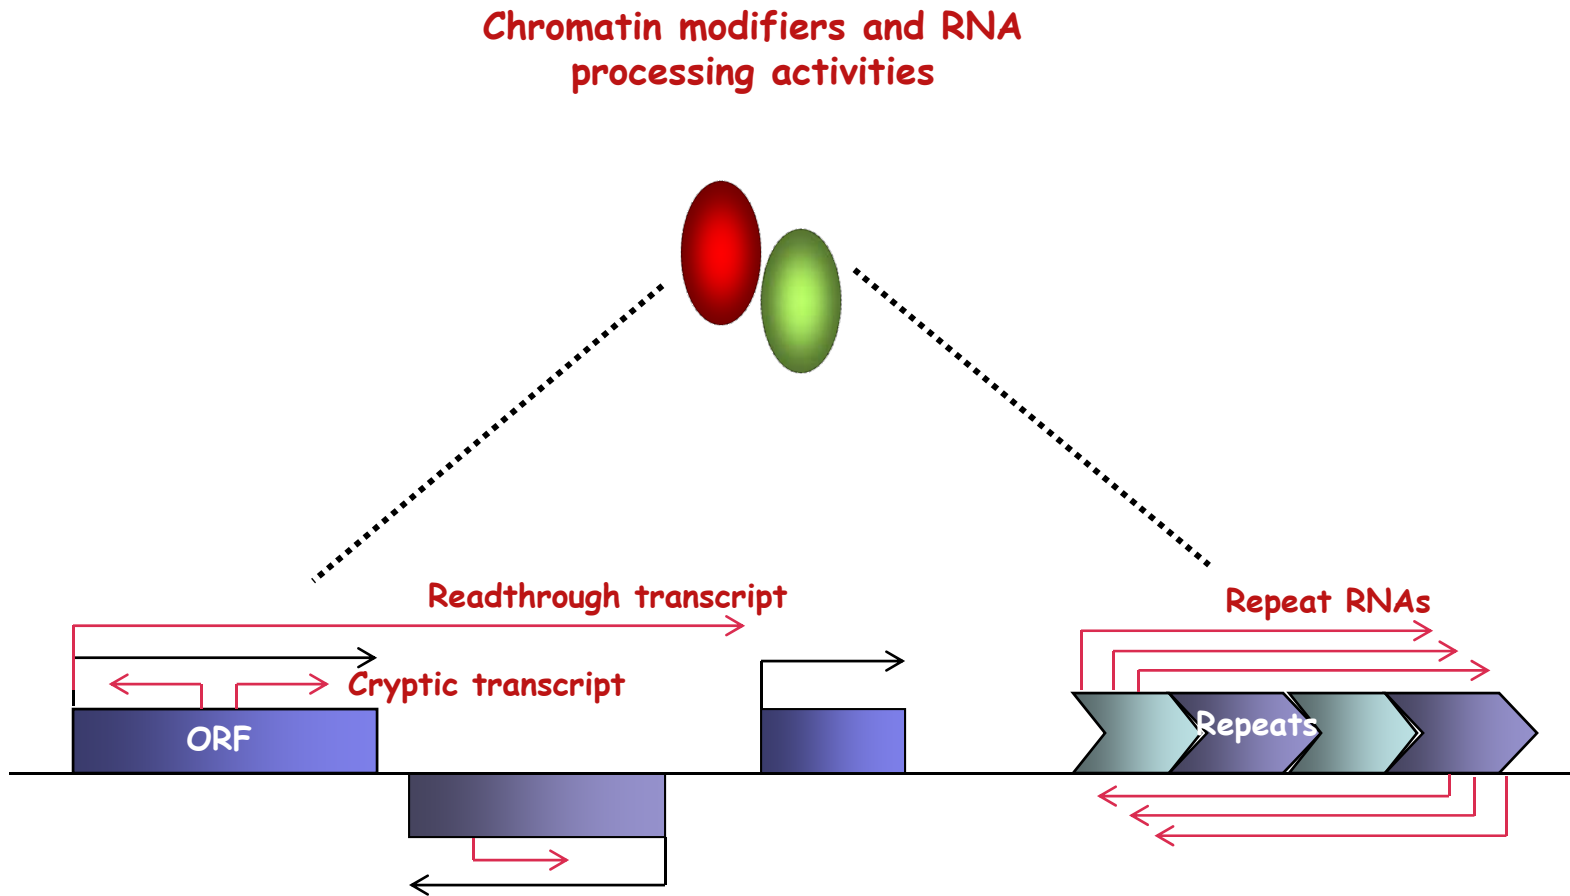

Center for Cancer Research

National Cancer Institute

Distinct levels of chromatin organization

Chromatin modifiers and RNA processing factors suppress transcriptional "noise" across genome

Accumulation of aberrant RNAs can lead to genomic instability

RNAi and heterochromatin factors cooperate with a variant histone H2A.Z to suppress antisense RNAs

Chromatin modifiers and RNA processing activities

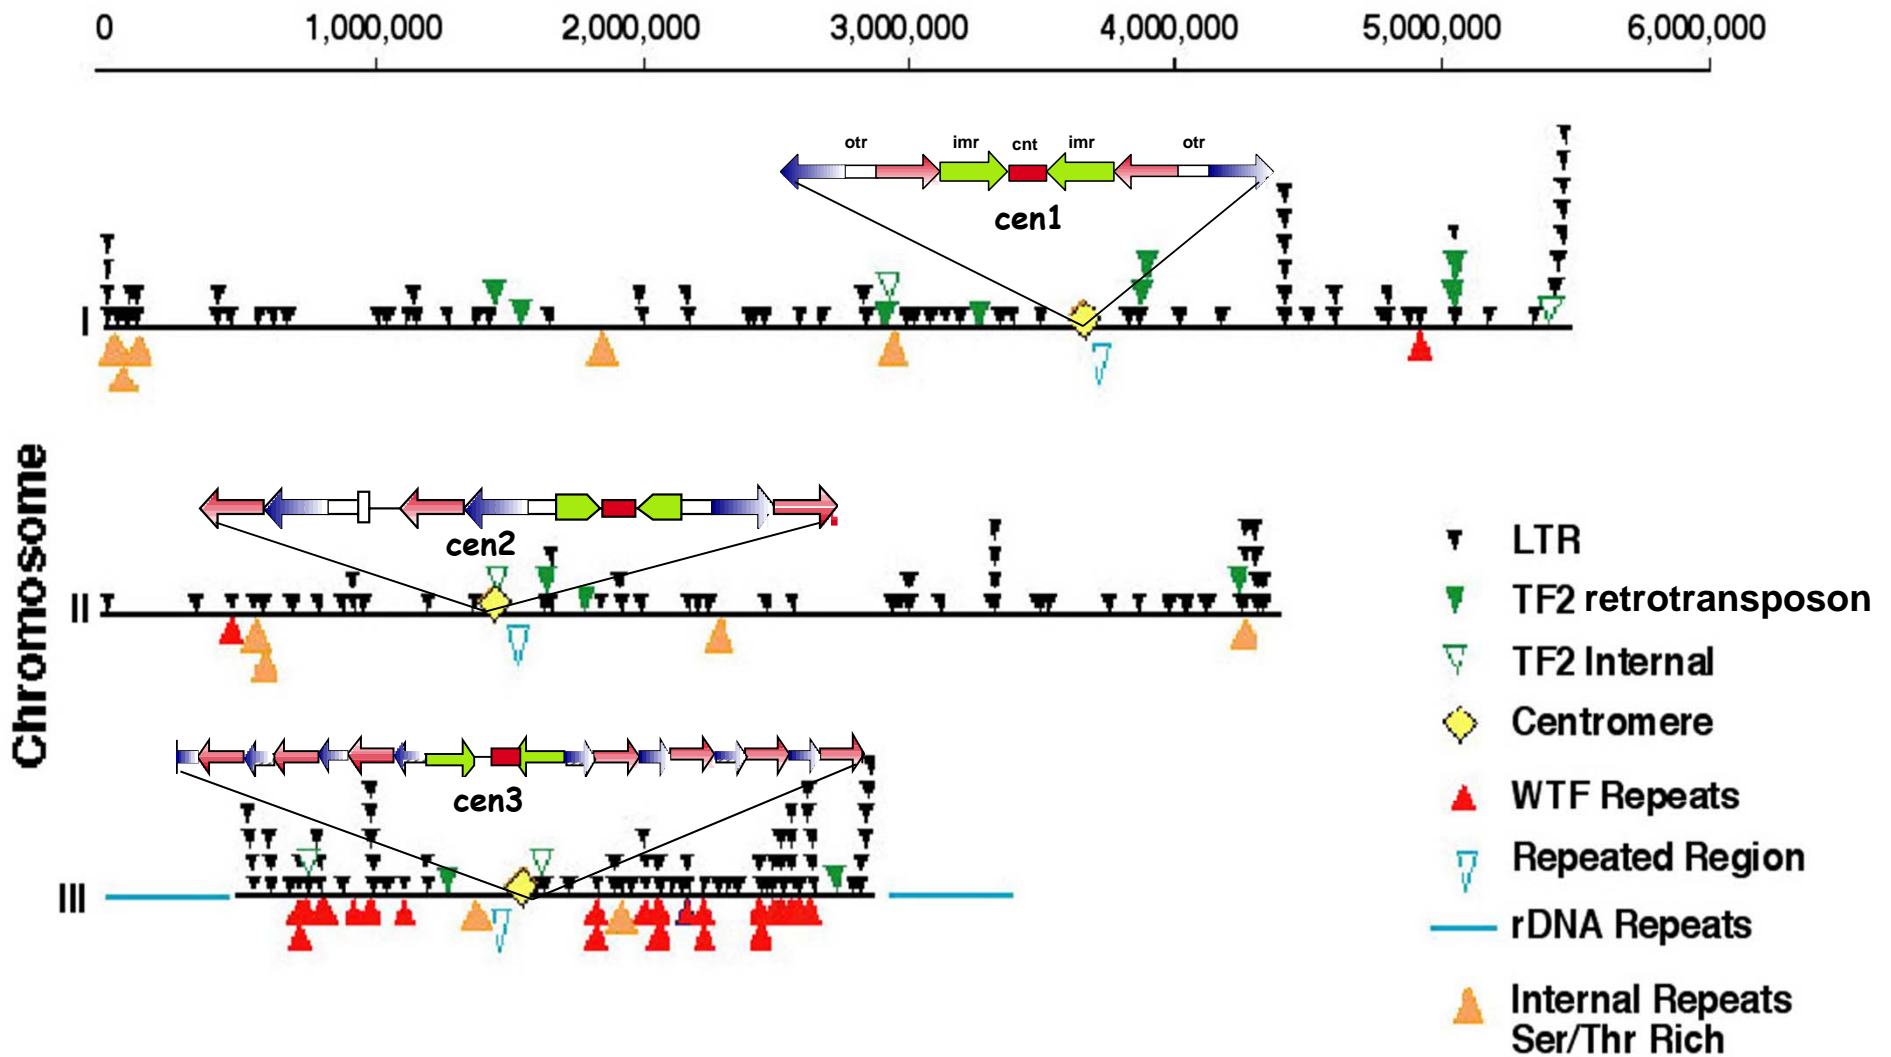

Accumulation of aberrant RNAs can lead to genomic instability

Topics:

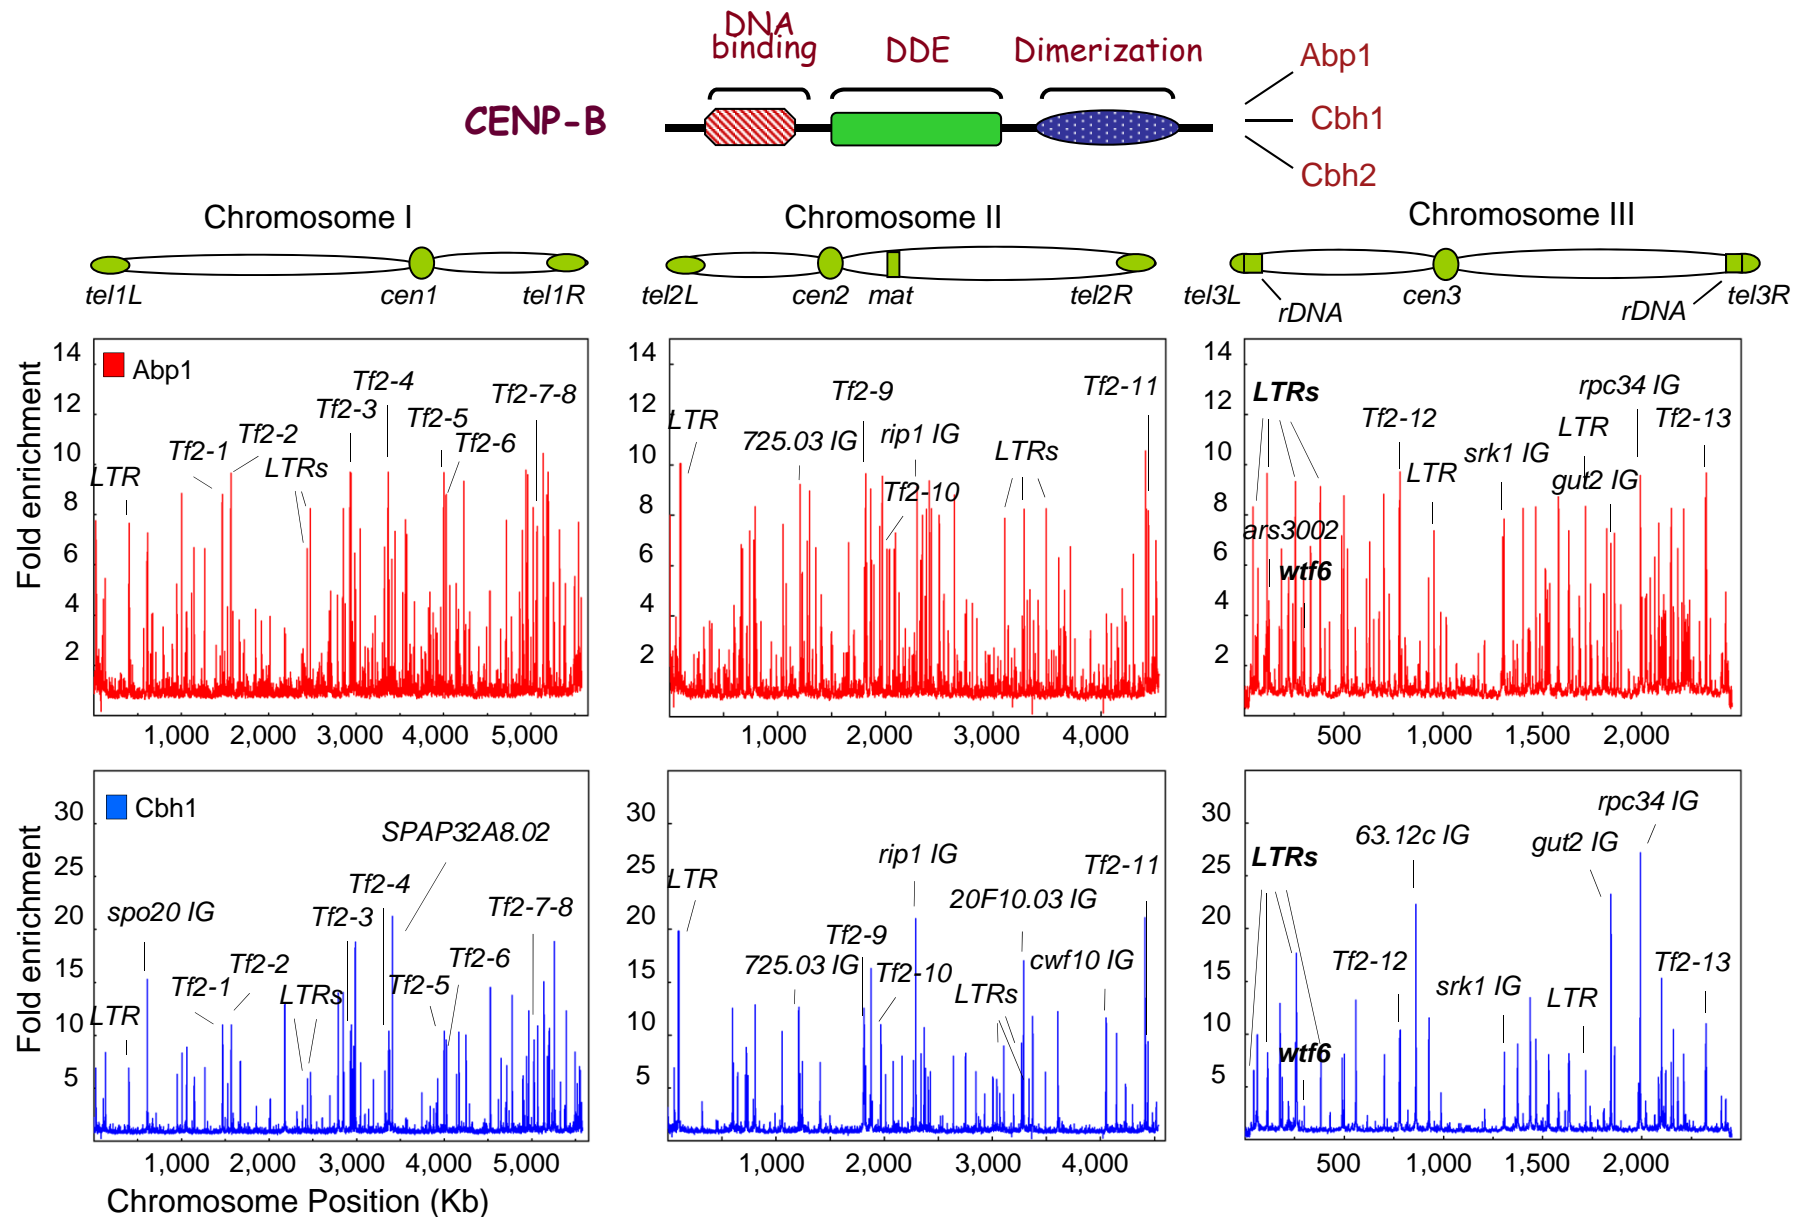

- Silencing of retrotransposons and repeat elements by RNAi and chromatin-modifying factors
- Genome-wide suppression of antisense RNAs by a variant histone and the RNAi machinery

S. pombe genome contains several classes of repeat elements that are assembled in repressive chromatin

All retroelements are bound by transposase-derived CENP-B proteins (Cam et al Nature 2008)

CENP-Bs localize to retrotransposons and their remnants in the *S. pombe* genome

CENP-Bs recruit Clr3 and Clr6 histone deacetylases to repress Tf2 retroelements

IP Western

Clr3 = SHREC

Clr6 HDAC

CENP-Bs recruit SHREC and Clr6 histone deacetylases to repress Tf2 retroelements

Transcriptional and
recombinational
suppression

CENP-Bs and their associated HDACs protect integrity of the genome

Tf1-neo expression

CENP-B proteins → Ctr3 & Ctr6 HDACs, other effectors

Gene regulatory networks

Maintenance of genome stability

Pulse-field Electrophoresis

neo^R colonies

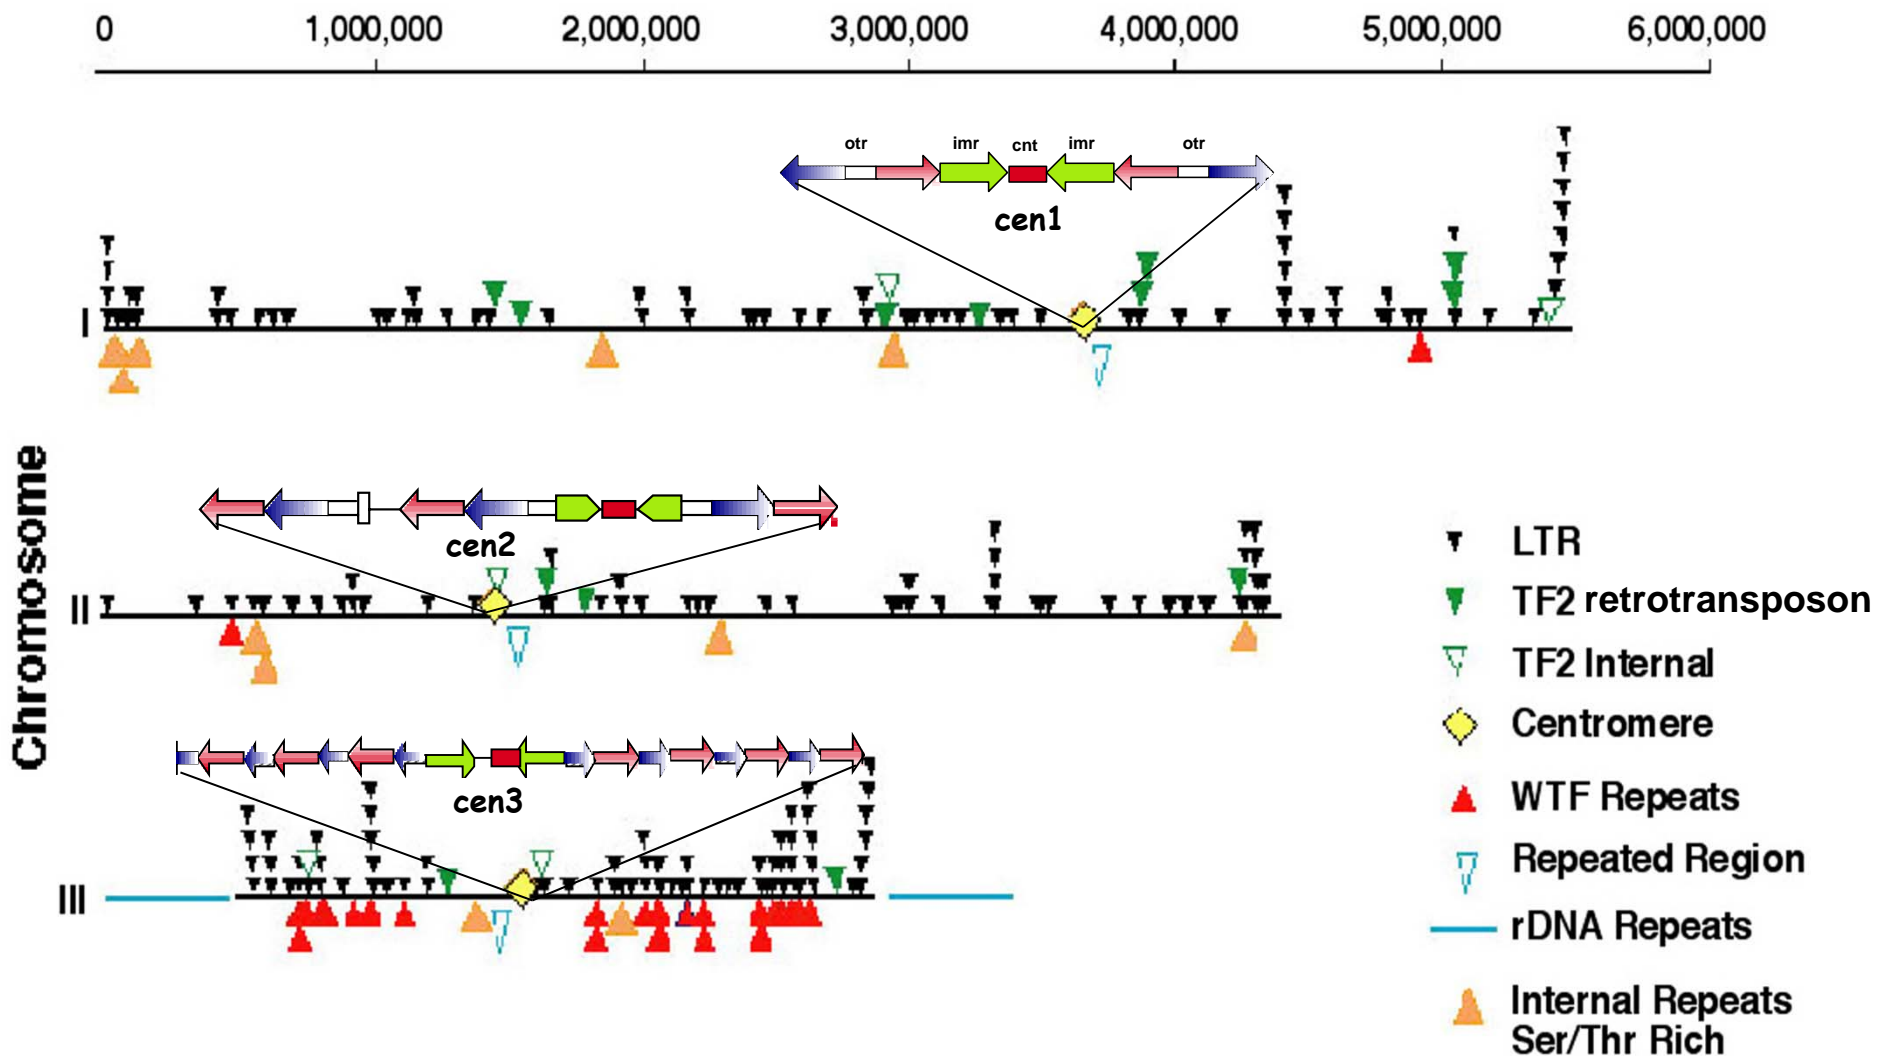

SHREC activities facilitate positioning of nucleosomes to suppress transcriptional "noise"

Micrococcal nuclease digestion patterns

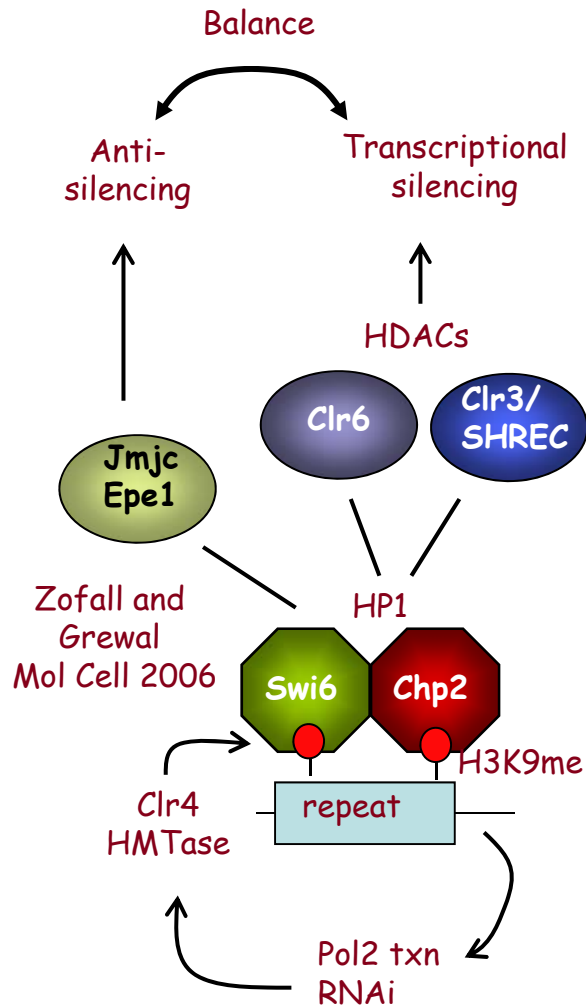

S. pombe genome contains several classes of repeat elements that are assembled in repressive chromatin

Heterochromatin: a versatile recruiting platform

HP1 proteins and their associated HDACs collaborate to enforce heterochromatic transcriptional silencing

Topics:

➤ Silencing of retrotransposons and repeat elements by RNAi and chromatin-modifying factors

➤ Genome-wide suppression of aberrant RNAs by a variant histone and the RNAi machinery

Large proportion (>90%) of the *S. pombe* genome including the intergenic regions are transcribed in both directions

Dutrow et al 2008 (Cairns lab)
Wilhelm et al 2008 (Bahler lab)
Nicolas et al 2007 (Our lab)

RNAi and heterochromatin factors cooperate with a variant histone H2A.Z to suppress antisense RNAs

Chromatin modifiers and RNA processing activities

Accumulation of aberrant RNAs can lead to genomic instability

H2A.Z is enriched at 5' ends of genes

ChIP profiling of H2A.Z

- H2AZ is a histone H2.A variant that is deposited onto chromatin by the SWR-C

- Loss of H2A.Z affects various chromosomal processes but its exact function is not known

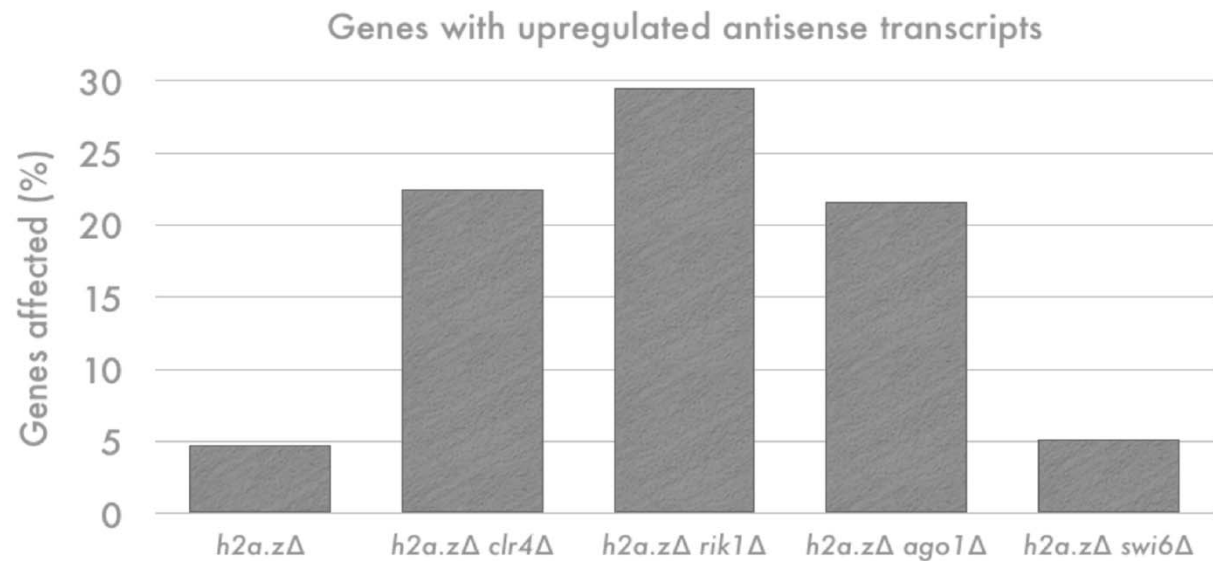

Loss of H2A.Z (pht1) causes disproportionate increase in antisense transcripts at convergent gene loci

Strand-specific RT-PCR

H2A.Z acts synergistically with Clr4 and Ago1 to suppress antisense transcripts

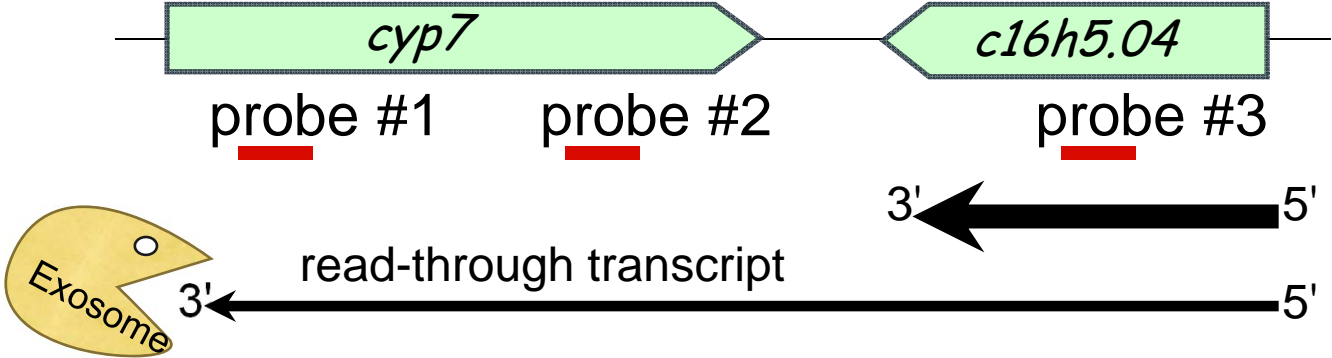

Antisense RNAs correspond to read-through transcripts rather than new initiation events

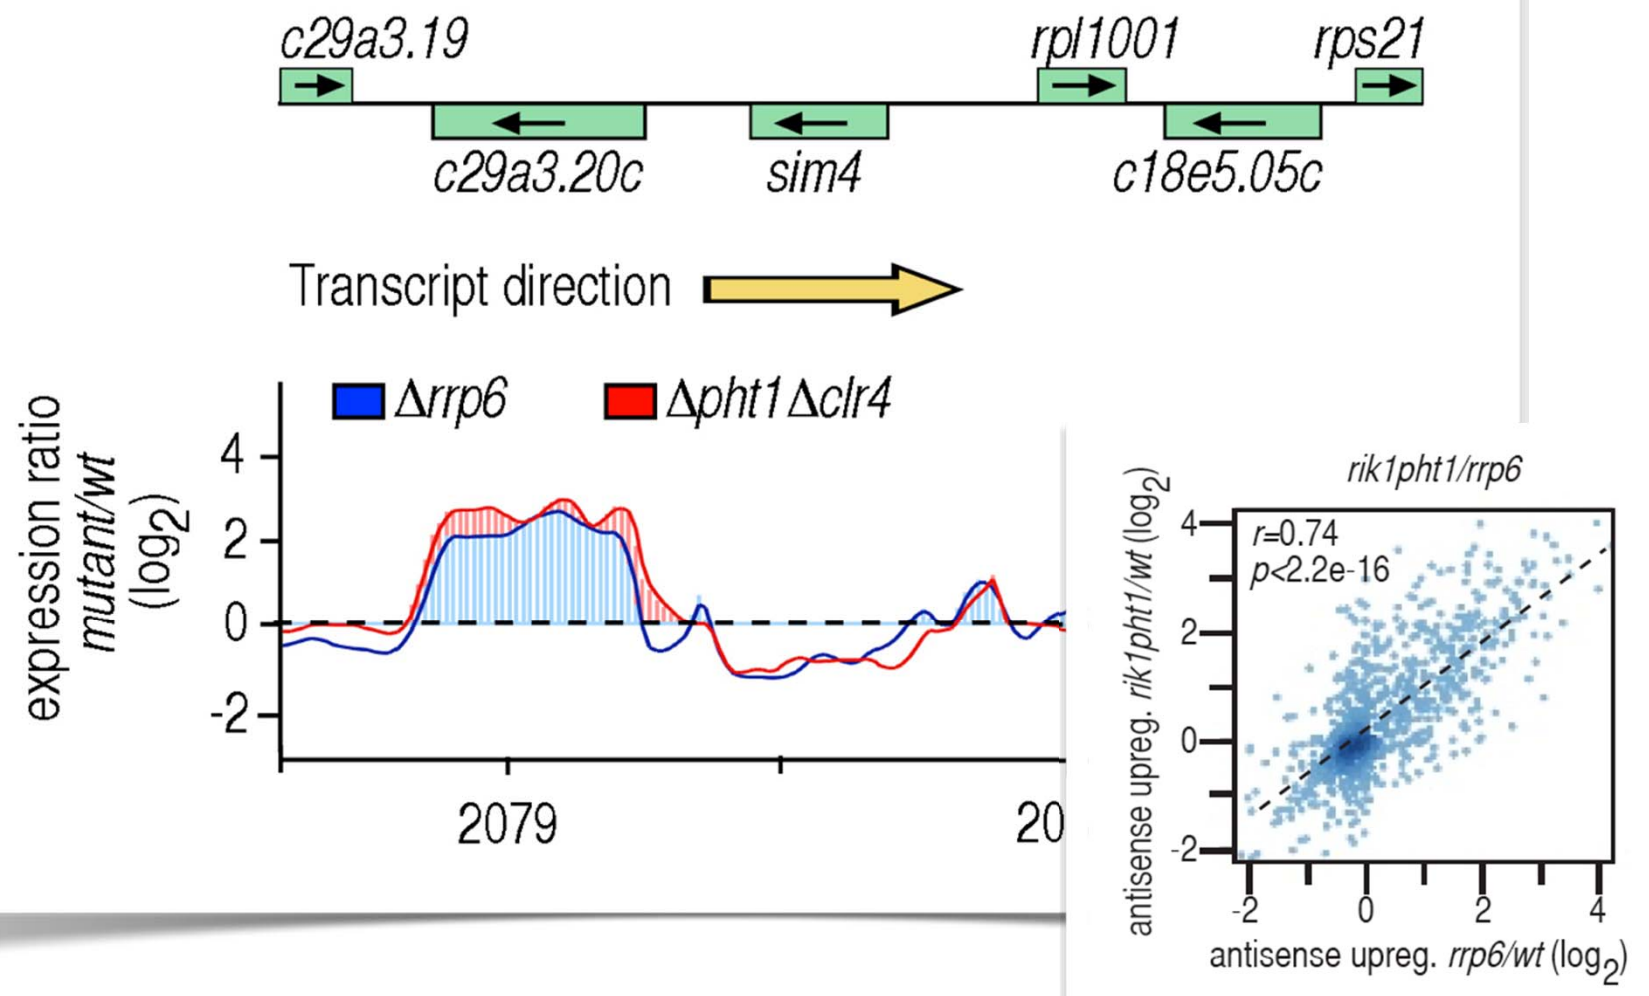

elevated RNA level → increased transcription
 elevated RNA level → increased RNA stability

Readthrough antisense RNAs accumulate in exosome (rrp6) mutant

Loss of exosome causes upregulation of antisense transcripts in a pattern identical to H2A.Z *clr4* mutant

H2A.Z and Pol II-associated Ago1 are components of RNA quality control mechanism involved in antisense suppression

Summary

- Transposon-derived CENP-B proteins and RNAi target chromatin modifying activities which in turn facilitate nucleosome positioning to suppress transcriptional noise at repeat elements
- H2A.Z is a component of genome indexing mechanism that cooperates with RNAi and heterochromatin factors to suppress antisense RNAs
